Number System

Basics of Number System

(1). Face Value : It is nothing but the number itself about which it has been asked.

Eg: In the number 23576, face value of 5 is 5 and face value of 7 is 7.

(2). Place Value : The place value of a number depends on its position in the number. Each position has a value 10^n , the places to its right.

Eg: In the number 23576, place value of 5 is 500 and place value of 3 is 3000.

Types of Numbers

(1). Natural Numbers (N) :

All positive counting numbers. (0 is not included in it.)

Examples: 1, 2, 3, 4 ... etc.

(2). Whole Numbers (W): All non-negative numbers are all whole numbers.

Examples: 0, 1, 2, 3, 4... etc.

(3). Integer Numbers (I): All positive numbers and negative numbers including zero. Positive numbers are called positive integers and negative numbers are called negative integers.

$I = \dots, -4, -3, -2, -1, 0, 1, 2, 3, 4 \dots$

(4). Even Numbers : 2, 4, 6, 8, 10....
[Divisible by 2 completely]

(5). Odd Numbers : 1, 3, 5, 7, 9, 11.... [Not divisible by 2 completely]

(6). Rational Numbers : Numbers whose exact value can be determined. Also a number which can be written in the form

$\frac{p}{q}$, where p and q are integers and $q \neq 0$ is called a rational number. For example,

Examples: $\frac{3}{4} = 0.75, \frac{4}{5} = 0.8, \frac{9}{-5}, \frac{22}{7}$

(7). Irrational Numbers : Numbers whose exact value cannot be determined.

Example: $\pi = 3.142857142857 \dots$

(8). Prime number : A number which is divisible by 1 and itself. 2 is only an even prime number

Example: 2, 3, 5, 7, 11, etc.

Note:-

Total prime no. between 1 - 50 $\Rightarrow$ 15

Total prime no. between 1 - 100 $\Rightarrow$ 25

Total prime no. between 1 - 500 $\Rightarrow$ 95

Total prime no. between 1 - 1000 $\Rightarrow$ 168

(9). Composite number : If we remove all prime numbers from natural numbers

then whatever is left is called Composite numbers.

Example: 4, 6, 8, 9, 10, 12 etc.

Note :- 1 is neither prime nor composite.

(10). Co - prime number : Two numbers are called Co-prime numbers if their HCF is 1.

Example : (2 and 3), (6 and 11).

Note : Two prime numbers are always co-prime numbers to each other. Any two consecutive integers are always co-prime numbers to each other.

Factors

The factors of a number are the numbers that divide it completely without leaving any remainder.

Example : 24 can be completely divided by 1, 2, 3, 4, 6, 8, 12 and 24, so these numbers are factors of 24.

Prime factorisation of a number : When a number is written in the form of multiplication of its prime factors, it's called prime factorisation.

Prime factorisation of 24.

2	24
2	12
2	6
	3

$$24 \rightarrow 2 \times 2 \times 2 \times 3 \text{ or } 2^3 \times 3^1$$

Number of factors : To find the number of factors we write the number in the form of prime factors and then add +1 to the exponent of prime factors and multiply them.

For example: $24 = 2^3 \times 3^1$

Number of factors of $24 \rightarrow (3+1)(1+1) = 4 \times 2 = 8$.

With the help of an example, we try to find the sum of all factors of a number.

$$24 = 2^3 \times 3^1,$$

$$\text{Sum of all factors} = (2^0 + 2^1 + 2^2 + 2^3) \times (3^0 + 3^1) = 15 \times 4 = 60.$$

Number of even factors of a number : To find the number of even factors of a number we add +1 to the exponents of prime numbers except 2.

(Note : If a number doesn't have 2 as its factor it will have 0 even factors)

Que. Find the number of even factors of 120.

$$\text{Ans. } 120 = 2^3 \times 3^1 \times 5^1$$

$$\text{Number of even factors} = 3 \times (1+1) \times (1+1) = 3 \times 2 \times 2 = 12$$

Note :- To find the sum of even factors, we shall ignore 2^0 ,

Que. Find the sum of even factors of 120.

$$\text{Sol:- Sum of even factors} = (2^1 + 2^2 + 2^3)(3^0 + 3^1)(5^0 + 5^1) = 14 \times 4 \times 6 = 336.$$

Number and Sum of odd factors of a number : To find the number and sum of odd factors of a number we have to ignore the exponents of 2.

Que. Find the number of odd factors 120.

$$\text{Sol:- } 120 = 2^3 \times 3^1 \times 5^1$$

$$\text{Required number} = (1+1)(1+1) = 4$$

The exponent of 2 is completely ignored.

$$\text{Sum of odd factors of } 120 = (3^0 + 3^1)(5^0 + 5^1) = 4 \times 6 = 24$$

Some Important Results of Factors:

$$1001 = 7 \times 11 \times 13$$

$$1001 \times abc = abcabc$$

$$1001 \times 234 = 234234$$

Que: Which of the following is a factor of 531531?

(a) 15 (b) 13 (c) 11 (d) both b and c

$$\text{Sol:- } 531531 = 1001 \times 531$$

$= 7 \times 11 \times 13 \times 531$ So, both 11 and 13 are factors of 531531.

$$111 = 37 \times 3, 1001 \times 111 = 111111,$$

When a single digit is written 6 times, 3, 7, 11, 13, and 37 are factors of it.

Que. Which of the following is a factor of 222222?

(a) 17 (b) 57 (c) 68 (d) 74

$$\text{Sol:- } 222222 = 2 \times 111111$$

$$= 2 \times 3 \times 7 \times 11 \times 13 \times 37$$

Clearly $2 \times 37 = 74$ is one of the factors.

$\rightarrow$ If a, b and c are prime numbers, then the number of prime factors of $a^x \times b^y \times c^z$ is $(x+y+z)$.

Recurring Decimal

Recurring decimals are referred to as numbers that are uniformly repeated after the decimal. Some rational numbers produce recurring decimals after converting them into decimal numbers, but all irrational numbers produce recurring decimals after converting them into decimal form.

Examples :

$$(1) \frac{1}{3} = 0.3333333 \dots = 0.\bar{3}$$

$$(2) 0.\bar{9} = \frac{9}{9} = 1$$

$$(3) 0.5\bar{37} = \frac{537 - 53}{990} = \frac{5274}{990}$$

$$(4) 2.5\bar{37} = 2 + \frac{537 - 53}{990} = 2 + \frac{5274}{990}$$

Divisibility Test

By 2:- When last digit is 0 or an even

number eg: 520, 588

By 3:- Sum of digits is divisible by 3
eg: 1971, 1974

By 4:- When last two digits are divisible by 4 or, they are zeros eg: 1528, 1700

By 5 :- When last digit is 0 or 5
eg: 1725, 1790

By 6 :- When the number is divisible by 2 and 3 both. eg: 36, 72

By 7 :- Subtract twice the last digit from the number formed by the remaining digits. Like 651 divisible by 7
 $65 - (1 \times 2) = 63$. Since 63 is divisible by 7, so is 651.

By 8 :- When the last three digits are divisible by 8. eg: 2256

By 9 :- When sum of digit is divisible by 9
eg: 9216

By 10 :- When the last digit is 0. eg: 452600

By 11:- When the difference between the sum of odd and even place digits is equal to 0 or multiple of 11.
eg: 217382

Sum of odd place digits = $2 + 7 + 8 = 17$

Sum of even place digits = $1 + 3 + 2 = 6$

$17 - 6 = 11$, hence 217382 is divisible by 11.

By 13 :- If adding four times the last digit to the number formed by the remaining digits is divisible by 13, then the number is divisible by 13. Like 1326 is divisible by 13

$132 + (6 \times 4) = 156$. Repeat the same process for 156.

$15 + (6 \times 4) = 39$. so 39 is divisible by 13

By 17 :- The divisibility rule of 17 states, "If five times the last digit is subtracted from a number made up of the remaining digits and the remainder is either 0 or a multiple of 17, then the number is divisible by 17".

Like 221: $22 - 1 \times 5 = 17$.

Prime Number Test

For finding whether any number is a prime number or not, we need to find the nearest square root of given number then we need to find out whether the given number is divisible by any prime number less than the obtained number or not. If it is divisible then it is not a prime number and if not divisible then it is a prime number

Example : Find whether 177 is a prime

number or not.

Soln : Nearest square root of 177 is 13. Now we need to check whether 177 is divisible by prime numbers less than 13. On checking we find that 177 is divisible by 3. Hence, 177 is not a prime number.

Important Formulas

Number of Zeros in an expression

We shall understand this concept with the help of an example.

Let's find the number of zeros in the following expression: $24 \times 32 \times 17 \times 23 \times 19 = (2^3 \times 3^1) \times 2^5 \times 17 \times 23 \times 19$

Notice that a zero is made only when there is a combination of 2 and 5. Since there is no '5' here there will be no zero in the above expression.

Example:-

$$8 \times 15 \times 23 \times 17 \times 25 \times 22 =$$

$2^3 \times (3^1 \times 5^1) \times 23 \times 17 \times 5^2 \times 2^1 \times 11$
In this expression there are 4 twos and 3 fives. From this 3 pairs of 5×2 can be formed. Therefore, there will be 3 zeros in the final product.

Que. Find the number of zeros in the value of:

$$2^2 \times 5^4 \times 4^6 \times 10^8 \times 6^{10} \times 15^{12} \times 8^{14} \times 20^{16} \times 10^{18} \times 25^{20}$$

Sol:-

$$2^2 \times 5^4 \times 4^6 \times 10^8 \times 6^{10} \times 15^{12} \times 8^{14}$$

$$\times 20^{16} \times 10^{18} \times 25^{20} =$$

$$2^2 \times 5^4 \times 2^{12} \times 2^8 \times 5^8 \times 2^{10} \times 3^{10} \times 3^{12} \times 5^{12} \times 2^{12} \times 2^{12} \times 5^{16} \times 2^{18} \times 5^{18} \times 5^{40}$$

Zeros are possible with a combination of 2×5 . Here the number of 5s are less so the number of zeros will be limited to the number of 5s.

In this expression number of fives are:

$$5^4 \times 5^8 \times 5^{12} \times 5^{16} \times 5^{18} \times 5^{40};$$

$$\text{i.e. } 4 + 8 + 12 + 16 + 18 + 40 = 98$$

The number of Zeros in $n!$

To find the number of zeros in $n!$, we divide 'n' by 5 until we get a number less than 5, and then we add all the quotients so obtained.

Que. Find the number of zeros in $36!$.

5	36	
5	7	(1)
	1	(2)

The number of zeros = $7 + 1 = 8$.

Remainder Theorem

Que. What will be the remainder when 17×23 is divided by 12?

Ans :- We can express this as:

$$17 \times 23 = (12 + 5) \times (12 + 11) = 12 \times 12 + 12 \times 11 + 5 \times 12 + 5 \times 11$$

In the above expression we will find that remainder will depend on the last term i.e. 5×11

$$\text{Now rem. } \left(\frac{5 \times 11}{12}\right) = 7.$$

$$\text{So, } \frac{12 \times 12 + 12 \times 11 + 5 \times 12 + 5 \times 11}{12}$$

and $\frac{5 \times 11}{12}$ remainder is same in both cases which is 7.

Example:- Remainder when

$1421 \times 1423 \times 1425$ is divided by 12?

$$\text{rem. } \left(\frac{1421 \times 1423 \times 1425}{12}\right)$$

$$= \text{rem. } \left(\frac{5 \times 7 \times 9}{12}\right) = \text{rem. } \left(\frac{35 \times 9}{12}\right)$$

$$= \text{rem. } \left(\frac{11 \times 9}{12}\right) = 3$$

Negative Remainder

Taking a negative remainder will make our calculation easier

Examples

$$(i) \text{ rem. } \left(\frac{7 \times 8}{9}\right) = \text{rem. } \left(\frac{-2 \times -1}{9}\right)$$

$$= -2 \times -1 = 2$$

$$(ii) \text{ rem. } \left(\frac{55 \times 56}{57}\right) = \text{rem. } \left(\frac{-2 \times -1}{57}\right)$$

$$= -2 \times -1 = 2$$

$$(iii) \text{ rem } \left(\frac{7 \times 10}{9} \right) = \text{rem } \left(\frac{-2 \times 1}{9} \right)$$

$$= -2 \times 1 = -2 \text{ or } 7$$

Large Power Concepts

Look at the following examples:

$$(i) \text{ rem } \left(\frac{28^{12345}}{9} \right) = \text{rem } \left(\frac{(27+1)^{12345}}{9} \right)$$

$$= \text{rem } \left(\frac{1^{12345}}{9} \right) = 1^{12345} = 1$$

$$(ii) \text{ rem } \left(\frac{26^{12345}}{9} \right)$$

$$= \text{rem } \left(\frac{(27-1)^{12345}}{9} \right)$$

$$= \text{rem } \left(\frac{-1^{12345}}{9} \right) = -1^{12345} = -1 \text{ or } 8$$

Application of Remainder Theorem

Que. Find the last two digits of the expression

$$22 \times 31 \times 44 \times 27 \times 37 \times 43 ?$$

Sol:- If we divide the above expression by 100, we will get the last two digits as remainder.

$$\Rightarrow \text{rem } \left(\frac{22 \times 31 \times 44 \times 27 \times 37 \times 43}{100} \right),$$

dividing by 4 to make it simple

$$= \text{rem } \left(\frac{22 \times 31 \times 11 \times 27 \times 37 \times 43}{25} \right)$$

$$= \text{rem } \left(\frac{132 \times 22 \times 216}{25} \right)$$

$$= \text{rem } \left(\frac{7 \times 22 \times 16}{25} \right) \Rightarrow \text{rem } \left(\frac{4 \times 16}{25} \right)$$

$$= \text{rem } \left(\frac{14}{25} \right) = 14$$

Since we had divided by 4 initially now to get the correct answer we need to multiply the remainder by 4.

So remainder will be $14 \times 4 = 56$, which will also be the last two digits of the expression.
